No part of this publication may be reproduced in any form, in an electronic retrieval system or otherwise, without the prior written permission of the publisher.

IEEE Standards documents are developed within the IEEE Societies and the Standards Coordinating Committees of the IEEE Standards Association (IEEE-SA) Standards Board. The IEEE develops its standards through a consensus development process, approved by the American National Standards Institute, which brings together volunteers representing varied viewpoints and interests to achieve the final product. Volunteers are not necessarily members of the Institute and serve without compensation. While the IEEE administers the process and establishes rules to promote fairness in the consensus development process, the IEEE does not independently evaluate, test, or verify the accuracy of any of the information contained in its standards.

Use of an IEEE Standard is wholly voluntary. The IEEE disclaims liability for any personal injury, property or other damage, of any nature whatsoever, whether special, indirect, consequential, or compensatory, directly or indirectly resulting from the publication, use of, or reliance upon this, or any other IEEE Standard document.

The IEEE does not warrant or represent the accuracy or content of the material contained herein, and expressly disclaims any express or implied warranty, including any implied warranty of merchantability or fitness for a specific purpose, or that the use of the material contained herein is free from patent infringement. IEEE Standards documents are supplied **“AS IS.”**

The existence of an IEEE Standard does not imply that there are no other ways to produce, test, measure, purchase, market, or provide other goods and services related to the scope of the IEEE Standard. Furthermore, the viewpoint expressed at the time a standard is approved and issued is subject to change brought about through developments in the state of the art and comments received from users of the standard. Every IEEE Standard is subjected to review at least every five years for revision or reaffirmation. When a document is more than five years old and has not been reaffirmed, it is reasonable to conclude that its contents, although still of some value, do not wholly reflect the present state of the art. Users are cautioned to check to determine that they have the latest edition of any IEEE Standard.

In publishing and making this document available, the IEEE is not suggesting or rendering professional or other services for, or on behalf of, any person or entity. Nor is the IEEE undertaking to perform any duty owed by any other person or entity to another. Any person utilizing this, and any other IEEE Standards document, should rely upon the advice of a competent professional in determining the exercise of reasonable care in any given circumstances.

Interpretations: Occasionally questions may arise regarding the meaning of portions of standards as they relate to specific applications. When the need for interpretations is brought to the attention of IEEE, the Institute will initiate action to prepare appropriate responses. Since IEEE Standards represent a consensus of concerned interests, it is important to ensure that any interpretation has also received the concurrence of a balance of interests. For this reason, IEEE and the members of its societies and Standards Coordinating Committees are not able to provide an instant response to interpretation requests except in those cases where the matter has previously received formal consideration. At lectures, symposia, seminars, or educational courses, an individual presenting information on IEEE standards shall make it clear that his or her views should be considered the personal views of that individual rather than the formal position, explanation, or interpretation of the IEEE.

Comments for revision of IEEE Standards are welcome from any interested party, regardless of membership affiliation with IEEE. Suggestions for changes in documents should be in the form of a proposed change of text, together with appropriate supporting comments. Comments on standards and requests for interpretations should be addressed to:

Secretary, IEEE-SA Standards Board
445 Hoes Lane
Piscataway, NJ 08854
USA

Authorization to photocopy portions of any individual standard for internal or personal use is granted by the Institute of Electrical and Electronics Engineers, Inc., provided that the appropriate fee is paid to Copyright Clearance Center. To arrange for payment of licensing fee, please contact Copyright Clearance Center, Customer Service, 222 Rosewood Drive, Danvers, MA 01923 USA; +1 978 750 8400. Permission to photocopy portions of any individual standard for educational classroom use can also be obtained through the Copyright Clearance Center.

Introduction

This introduction is not part of IEEE Std 1619, IEEE Standard for Cryptographic Protection of Data on Block-Oriented Storage Devices.

The purpose of this standard is to describe a method of encryption for data stored in sector-based devices where the threat model includes possible access to stored data by the adversary. The standard specifies the encryption transform and a method for exporting/importing encryption keys for compatibility between different implementations. Encryption of data in transit is not covered by this standard.

This standard defines the XTS-AES tweakable block cipher and its use for encryption of sector-based storage. XTS-AES is a tweakable block cipher that acts on data units of 128 bits or more and uses the AES block cipher as a subroutine. The key material for XTS-AES consists of a data encryption key (used by the AES block cipher) as well as a “tweak key” that is used to incorporate the logical position of the data block into the encryption. XTS-AES is a concrete instantiation of the class of tweakable block ciphers described in Rogaway [B10].^a The XTS-AES addresses threats such as copy-and-paste attack, while allowing parallelization and pipelining in cipher implementations.

Notice to users

Laws and regulations

Users of these documents should consult all applicable laws and regulations. Compliance with the provisions of this standard does not imply compliance to any applicable regulatory requirements. Implementers of the standard are responsible for observing or referring to the applicable regulatory requirements. IEEE does not, by the publication of its standards, intend to urge action that is not in compliance with applicable laws, and these documents may not be construed as doing so.

Copyrights

This document is copyrighted by the IEEE. It is made available for a wide variety of both public and private uses. These include both use, by reference, in laws and regulations, and use in private self-regulation, standardization, and the promotion of engineering practices and methods. By making this document available for use and adoption by public authorities and private users, the IEEE does not waive any rights in copyright to this document.

Updating of IEEE documents

Users of IEEE standards should be aware that these documents may be superseded at any time by the issuance of new editions or may be amended from time to time through the issuance of amendments, corrigenda, or errata. An official IEEE document at any point in time consists of the current edition of the document together with any amendments, corrigenda, or errata then in effect. In order to determine whether a given document is the current edition and whether it has been amended through the issuance of amendments, corrigenda, or errata, visit the IEEE Standards Association website at <http://ieeexplore.ieee.org/xpl/standards.jsp>, or contact the IEEE at the address listed previously.

For more information about the IEEE Standards Association or the IEEE standards development process, visit the IEEE-SA website at <http://standards.ieee.org>.

^a The numbers in brackets correspond to those of the bibliography in Annex A.

Errata

Errata, if any, for this and all other standards can be accessed at the following URL: <http://standards.ieee.org/reading/ieee/updates/errata/index.html>. Users are encouraged to check this URL for errata periodically.

Interpretations

Current interpretations can be accessed at the following URL: <http://standards.ieee.org/reading/ieee/interp/index.html>.

Patents

Attention is called to the possibility that implementation of this standard may require use of subject matter covered by patent rights. By publication of this standard, no position is taken with respect to the existence or validity of any patent rights in connection therewith. The IEEE is not responsible for identifying Essential Patent Claims for which a license may be required, for conducting inquiries into the legal validity or scope of Patents Claims or determining whether any licensing terms or conditions provided in connection with submission of a Letter of Assurance, if any, or in any licensing agreements are reasonable or non-discriminatory. Users of this guide are expressly advised that determination of the validity of any patent rights, and the risk of infringement of such rights, is entirely their own responsibility. Further information may be obtained from the IEEE Standards Association.

Participants

The Security in Storage Working Group operated under the following sponsorship:

Sponsor: John L. Cole
Co-Sponsor: Curtis Anderson

At the time this standard was submitted to the IEEE-SA Standards Board for approval, the Security in Storage Working Group had the following officers:

Matthew V. Ball, *Chair*
Eric A. Hibbard, *Vice-chair*
James P. Hughes, *Past chair*
Fabio Maino, *Secretary*

At the time this standard was submitted to the IEEE-SA Standards Board for approval, the P1619 Task Group had the following membership:

Serge Plotkin, *Task Group Chair and Technical Editor*

Gideon Avida
Matthew V. Ball
David L. Black
Russel S. Dietz
Robert C. Elliott
Hal Finney
John Goldman
Robert W. Griffin
Cyril Guyot

Shai Halevi

IEEE Standard for Cryptographic Protection of Data on Block-Oriented Storage Devices

IMPORTANT NOTICE: This standard is not intended to assure safety, security, health, or environmental protection in all circumstances. Implementers of the standard are responsible for determining appropriate safety, security, environmental, and health practices or regulatory requirements.

This IEEE document is made available for use subject to important notices and legal disclaimers. These notices and disclaimers appear in all publications containing this document and may be found under the heading "Important Notice" or "Important Notices and Disclaimers Concerning IEEE Documents." They can also be obtained on request from IEEE or viewed at <http://standards.ieee.org/IPR/disclaimers.html>.

1. Overview

1.1 Scope

This standard specifies elements of an architecture for cryptographic protection of data on block-oriented storage devices, describing the methods, algorithms, and modes of data protection to be used.

1.2 Purpose

This standard defines specific elements of an architecture for cryptographically protecting data stored in constant length blocks. Specification of such a mechanism provides an additional and improved tool for implementation of secure and interoperable protection of data residing in storage.

1.3 Related work

The formal definition of the security goal of a tweakable block-cipher can be attributed to Liskov, Rivest, and Wagner [B5]¹, where they also show how tweakable ciphers can be built from standard block ciphers. An earlier work by Schroepel suggested the idea of a tweakable block-cipher, by designing a cipher that natively incorporates a tweak (see Schroepel [B11]).

¹ The numbers in brackets correspond to those of the bibliography in Annex A.

2. Normative references

The following referenced documents are indispensable for the application of this document (i.e., they must be understood and used, so each referenced document is cited in text and its relationship to this document is explained). For dated references, only the edition cited applies. For undated references, the latest edition of the referenced document (including any amendments or corrigenda) applies.

NIST FIPS-197, Federal Information Processing Standard (FIPS) for the Advanced Encryption Standard (AES).²

REC-xml, W3C Extensible Markup Language (XML) 1.0 (Fourth Edition).³

3. Definitions, acronyms, and abbreviations

3.1 Definitions

For the purposes of this standard, the following terms and definitions apply. *The Authoritative Dictionary of IEEE Standards Terms, Seventh Edition* [B4] should be referenced for terms not defined in this clause.

3.1.1 key scope: Data encrypted by a particular key, divided into equal-sized data units. The key scope is identified by three non-negative integers: tweak value corresponding to the first data unit, the data unit size, and the length of the data.

NOTE—See 4.3.1.⁴

3.1.2 tweak value: The 128-bit value used to represent the logical position of the data being encrypted or decrypted with XTS-AES.

3.2 Acronyms and abbreviations

AES	advanced encryption standard
Base64	encoding according to IETF RFC 3548 [B12]
DTD	document type definition
FIPS	Federal Information Processing Standard
GF	Galois field (see Menezes et. al. [B6])
LBA	logical block address
XML	extensible markup language
XTS	XEX encryption mode with tweak and ciphertext stealing

4. Special terms

4.1 Numerical values

Decimal and binary numbers are used within this document. For clarity, decimal numbers are generally used to represent counts and binary numbers are used to describe bit patterns.

² FIPS publications are available from the National Technical Information Service, 5285 Port Royal Road, Springfield, VA 22661, USA. FIPS-197 is also available on-line from <http://csrc.nist.gov/publications/fips/index>.

³ Available at <http://www.w3.org/TR/REC-xml/>

⁴ Notes in text, tables, and figures are given for information only, and do not contain requirements needed to implement the standard.

Decimal numbers are represented in their usual 0, 1, 2, ... format. Binary numbers are represented by a string of one or more bits followed by the subscript 2. Thus the decimal number 26 may also be represented as 00011010₂. Hexadecimal numbers are represented by a string of one or more hexadecimal characters followed by a subscript 16.

4.2 Letter symbols

The following symbols are used in equations and figures:

\oplus	Bit-wise exclusive-OR operation
\otimes	Modular multiplication of two polynomials over the binary field GF(2), modulo $x^{128} + x^7 + x^2 + x + 1$, where GF stands for Galois Field (see Menezes et. al. [B6])
α	A primitive element of GF(2 ¹²⁸) that corresponds to polynomial x (i.e., 0000...010 ₂), where GF stands for Galois Field (see Menezes et. al. [B6])
\bullet	Assignment of a value to a variable
	Concatenation (e.g., if K1 = 001 ₂ and K2 = 101010 ₂ , then K1 K2 = 001101010 ₂)
//	Start of a comment. Comment ends at end of line
$\lfloor x \rfloor$	Floor of x (e.g., $\lfloor 7/3 \rfloor = 2$)

4.3 Special definitions

4.3.1 Data unit: Within IEEE Std 1619, 128 or more bits of data within a key scope. The first data unit in a key scope starts with the first bit of the key scope; each subsequent data unit starts with the bit after the end of the previous data unit. Data units within a key scope are of equal sizes. A data unit does not necessarily correspond to a physical or logical block on the storage device.

5. XTS-AES transform

5.1 Data units and tweaks

This standard applies to encryption of a data stream divided into consecutive equal-size data units, where the data stream refers to the information that has to be encrypted and stored on the storage device. Information that is not to be encrypted is considered to be outside of the data stream.

The data unit size shall be at least 128 bits. Data unit should be divided into 128-bit blocks. Last part of the data unit might be shorter than 128 bits. The number of 128-bit blocks in the data unit shall not exceed $2^{128} - 2$. The number of 128-bit blocks should not exceed 2^{20} . Each data unit is assigned a tweak value that is a non-negative integer. The tweak values are assigned consecutively, starting from an arbitrary non-negative integer. When encrypting a tweak value using AES, the tweak is first converted into a little-endian byte array. For example, tweak value 123456789a₁₆ corresponds to byte array 9a₁₆, 78₁₆, 56₁₆, 34₁₆, 12₁₆.

The mapping between the data unit and the transfer, placement, and composition of data on the storage device is beyond the scope of this standard. Devices compliant with this standard should include

documentation describing this mapping. In particular, a single data unit does not necessarily correspond to a single logical block on the storage device. For example, several logical blocks might correspond to a single data unit. Data stream, as used in this standard, does not necessarily refer to all of the bits sent to be stored in the storage device. For example, if only part of a logical block is encrypted, only the encrypted bytes are viewed as the data stream, i.e., input to the encryption algorithm in this standard.

5.2 Multiplication by a primitive element α

The encryption procedure (see 5.3) and decryption procedure (see 5.4) use multiplication of a 16-byte value (the result of AES encryption or decryption) by j -th power of α , a primitive element of $\text{GF}(2^{128})$. The input value is first converted into a byte array $a_0[k]$, $k = 0, 1, \dots, 15$. In particular, the 16-byte result of AES encryption or decryption is treated as a byte array, where $a_0[0]$ is the first byte of the AES block.

This multiplication is defined by the following procedure:

Input: j is the power of α
byte array $a_0[k]$, $k = 0, 1, \dots, 15$
Output: byte array $a_j[k]$, $k = 0, 1, \dots, 15$

The output array is defined recursively by the following formulas where i is iterated from 0 to j :

$$\begin{aligned} a_{i+1}[0] &\leftarrow (2(a_i[0] \bmod 128)) \oplus (135 \lfloor a_i[15]/128 \rfloor) \\ a_{i+1}[k] &\leftarrow (2(a_i[k] \bmod 128)) \oplus \lfloor a_i[k-1]/128 \rfloor, \quad k = 1, 2, \dots, 15 \end{aligned}$$

NOTE—Conceptually, the operation is a left shift of each byte by one bit with carry propagating from one byte to the next one. Also, if the 15th (last) byte shift results in a carry, a special value (decimal 135) is xor-ed into the first byte. This value is derived from the modulus of the Galois Field (polynomial $x^{128} + x^7 + x^2 + x + 1$). See Annex C for an alternative way to implement the multiplication by α^j .

5.3 XTS-AES encryption procedure

5.3.1 XTS-AES-blockEnc procedure, encryption of a single 128-bit block

The XTS-AES encryption procedure for a single 128-bit block is modeled with Equation (1).

$$C \leftarrow \text{XTS-AES-blockEnc}(Key, P, i, j) \quad (1)$$

where

Key is the 256 or 512 bit XTS-AES key
 P is a block of 128 bits (i.e., the plaintext)
 i is the value of the 128-bit tweak (see 5.1)
 j is the sequential number of the 128-bit block inside the data unit
 C is the block of 128 bits of ciphertext resulting from the operation

The key is parsed as a concatenation of two fields of equal size called Key_1 and Key_2 such that:

$$Key = Key_1 \parallel Key_2.$$

The ciphertext shall then be computed by the following or an equivalent sequence of steps (see Figure 1):

- 1) $T \leftarrow \text{AES-enc}(Key_2, i) \otimes \alpha^j$
- 2) $PP \leftarrow P \oplus T$
- 3) $CC \leftarrow \text{AES-enc}(Key_1, PP)$
- 4) $C \leftarrow CC \oplus T$

AES-enc(K, P) is the procedure of encrypting plaintext P using AES algorithm with key K , according to FIPS-197. The multiplication and computation of power in step 1) is executed in $GF(2^{128})$, where α is the primitive element defined in 4.2 (see 5.2).

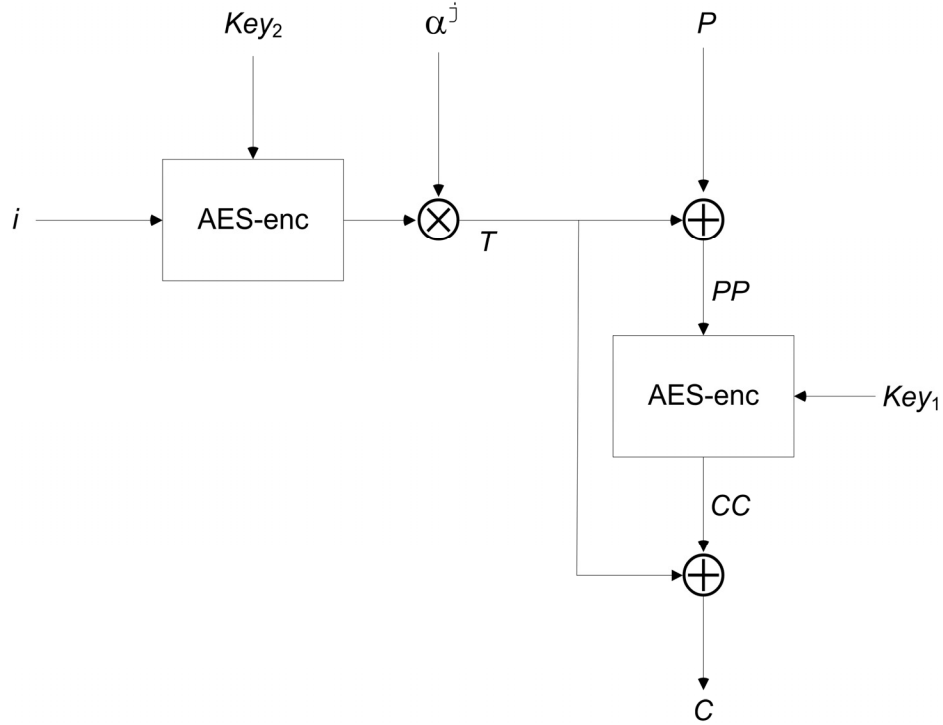

Figure 1— Diagram of XTS-AES blockEnc procedure

5.3.2 XTS-AES encryption of a data unit

The XTS-AES encryption procedure for a data unit of plaintext of 128 or more bits is modeled with Equation (2).

$$C \leftarrow \text{XTS-AES-Enc}(\text{Key}, P, i) \quad (2)$$

where

- Key is the 256 or 512 bit XTS-AES key
- P is the plaintext
- i is the value of the 128-bit tweak (see 5.1)
- C is the ciphertext resulting from the operation, of the same bit-size as P

The plaintext data unit is first partitioned into $m + 1$ blocks, as follows:

$$P = P_0 \parallel \dots \parallel P_{m-1} \parallel P_m$$

where m is the largest integer such that $128m$ is no more than the bit-size of P , the first m blocks P_0, \dots, P_{m-1} are each exactly 128 bits long, and the last block P_m is between 0 and 127 bits long (P_m could be empty, i.e., 0 bits long). The key is parsed as a concatenation of two fields of equal size called Key_1 and Key_2 such that: $\text{Key} = \text{Key}_1 \parallel \text{Key}_2$. The ciphertext C is then computed by the following or an equivalent sequence of steps:

- 1) for $q \leftarrow 0$ to $m-2$ do

```

a)  $C_q \leftarrow \text{XTS-AES-blockEnc}(Key, P_j, i, q)$ 
2)  $b \leftarrow \text{bit-size of } P_m$ 
3) if  $b = 0$  then do
a)  $C_{m-1} \leftarrow \text{XTS-AES-blockEnc}(Key, P_{m-1}, i, m-1)$ 
b)  $C_m \leftarrow \text{empty}$ 
4) else do
a)  $CC \leftarrow \text{XTS-AES-blockEnc}(Key, P_{m-1}, i, m-1)$ 
b)  $C_m \leftarrow \text{first } b \text{ bits of } CC$ 
c)  $CP \leftarrow \text{last } (128-b) \text{ bits of } CC$ 
d)  $PP \leftarrow P_m \parallel CP$ 
e)  $C_{m-1} \leftarrow \text{XTS-AES-blockEnc}(Key, PP, i, m)$ 
5)  $C \leftarrow C_0 \parallel \dots \parallel C_{m-1} \parallel C_m$ 

```

An illustration of encrypting the last two blocks $P_{m-1}P_m$ in the case that P_m is a partial block ($b > 0$) is provided in Figure 2.

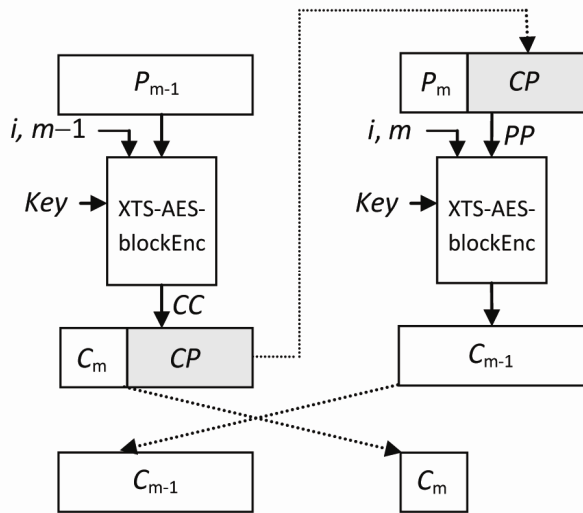

Figure 2—XTS-AES encryption of last two blocks when last block is 1 to 127 bits

5.4 XTS-AES decryption procedure

5.4.1 XTS-AES-blockDec procedure, decryption of a single 128-bit block

The XTS-AES decryption procedure of a single 128-bit block is modeled with Equation (3).

$$P \leftarrow \text{XTS-AES-blockDec}(Key, C, i, j) \quad (3)$$

where

Key is the 256 or 512-bit XTS-AES key
 C the 128-bit block of ciphertext
 i is the value of the 128-bit tweak (see 5.1)
 j is the sequential number of the 128-bit block inside the data unit

P is the 128-bit block of plaintext resulting from the operation

The key is parsed as a concatenation of two fields of equal size called Key_1 and Key_2 such that: $Key = Key_1 \parallel Key_2$. The plaintext shall then be computed by the following or an equivalent sequence of steps (see Figure 3):

- 1) $T \leftarrow \text{AES-enc}(Key_2, i) \otimes \alpha^j$
- 2) $CC \leftarrow C \oplus T$
- 3) $PP \leftarrow \text{AES-dec}(Key_1, CC)$
- 4) $P \leftarrow PP \oplus T$

$\text{AES-dec}(K, C)$ is the procedure of decrypting ciphertext C using AES algorithm with key K , according to FIPS-197. The multiplication and computation of power in step 1) is executed in $\text{GF}(2^{128})$, where α is the primitive element defined in 4.2 (see 5.2).

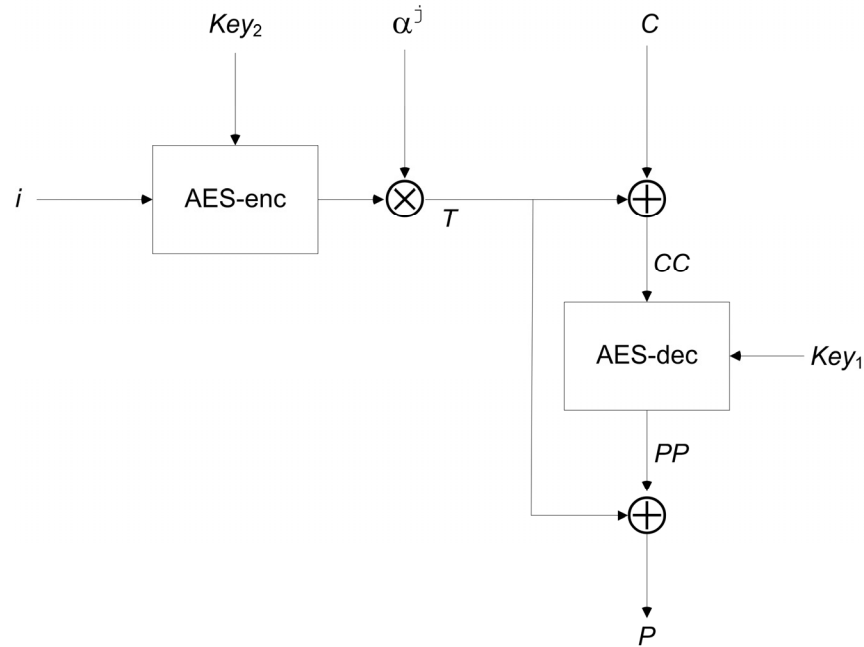

Figure 3—Diagram of XTS-AES blockDec procedure

5.4.2 XTS-AES decryption of a data unit

The XTS-AES decryption procedure for a data unit ciphertext of 128 or more bits is modeled with Equation (4).

$$P \leftarrow \text{XTS-AES-Dec}(Key, C, i) \quad (4)$$

where

- Key is the 256 or 512-bit XTS-AES key
- C is the ciphertext corresponding to the data unit
- i is the value of the 128-bit tweak (see 5.1)
- P is the plaintext data unit resulting from the operation, of the same bit-size as C

The ciphertext is first partitioned into $m + 1$ blocks as follows:

$$C = C_0 \parallel \dots \parallel C_{m-1} \parallel C_m$$

where m is the largest integer such that $128m$ is no more than the bit-size of C , the first m blocks C_0, \dots, C_{m-1} are each exactly 128 bits long, and the last block C_m is between 0 and 127 bits long (C_m could be empty, i.e., 0 bits long). The key is parsed as a concatenation of two fields of equal size called Key_1 and Key_2 such that: $Key = Key_1 \parallel Key_2$. The plaintext P is then computed by the following or an equivalent sequence of steps:

- 1) for $q \leftarrow 0$ to $m-2$ do
 - a) $P_q \leftarrow \text{XTS-AES-blockDec}(Key, C_j, i, q)$
- 2) $b \leftarrow \text{bit-size of } C_m$
- 3) if $b = 0$ then do
 - b) $P_{m-1} \leftarrow \text{XTS-AES-blockDec}(Key, C_{m-1}, i, m-1)$
 - c) $P_m \leftarrow \text{empty}$
- 4) else do
 - d) $PP \leftarrow \text{XTS-AES-blockDec}(Key, C_{m-1}, i, m)$
 - e) $P_m \leftarrow \text{first } b \text{ bits of } PP$
 - f) $CP \leftarrow \text{last } (128-b) \text{ bits of } PP$
 - g) $CC \leftarrow C_m \parallel CP$
 - h) $P_{m-1} \leftarrow \text{XTS-AES-blockDec}(Key, CC, i, m-1)$
- 5) $P \leftarrow P_0 \parallel \dots \parallel P_{m-1} \parallel P_m$

The decryption of the last two blocks $C_{m-1}C_m$ in the case that C_m is a partial block ($b > 0$) is illustrated in Figure 4.

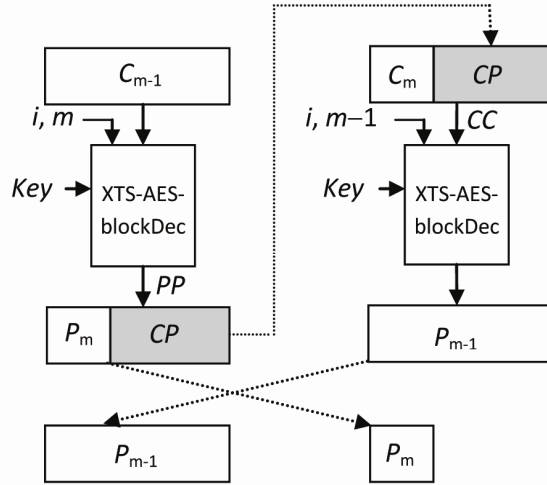

Figure 4—XTS-AES decryption of last two blocks when last block is 1 to 127 bits

6. Using XTS-AES-128 and XTS-AES-256 for encryption of storage

The encryption and decryption procedures described in 5.3 and 5.4 use AES as the basic building block. If the XTS-AES key consists of 256 bits, the procedures use 128-bit AES; if the XTS-AES key consists of 512 bits, the procedures use 256-bit AES. For completeness, the first mode shall be referred to as XTS-

AES-128 and the second as XTS-AES-256. To be compliant with the standard, the implementation shall support at least one of the above modes.

Key scope defines the range of data encrypted with a single XTS-AES key. As defined in 7.1.4, the key scope is represented by the following three values:

- a) Value of the tweak associated with the first data unit in the sequence of data units encrypted by this key
- b) The size in bits of each data unit
- c) The number of units to be encrypted/decrypted under the control of this key.

An implementation compliant with this standard may or may not support multiple data unit sizes.

In an application of this standard to sector-level encryption of a disk, the data unit typically corresponds to a logical block, the key scope typically includes a range of consecutive logical blocks on the disk, and the tweak value associated with the first data unit in the scope typically corresponds to the Logical Block Address (LBA) associated with the first logical block in the range.

An XTS-AES key shall not be associated with more than one key scope.

NOTE—The reason for the previous restriction is that encrypting more than one block with the same key and the same index introduces security vulnerabilities that might potentially be used in an attack on the system. In particular, key reuse enables trivial cut-and-paste attacks.

7. Exporting and archiving XTS-AES-128 and XTS-AES-256 keys

7.1 Key backup structure

7.1.1 Key backup structure overview

The system surrounding a device compliant with this standard should support the key backup structure defined in this clause. The XML (see REC-xml) representation of key backup structure is presented in 7.2. The key backup structure provides all the information that is needed in order to decrypt an integral number of data units that were encrypted with XTS-AES-[128,256]. These data units are assumed to be a contiguous sequence, with a given tweak value (KeyScopeStart element in Table 4) associated with the first data unit.⁵ For example, if the input data units are on a single physical medium, the initial tweak value can correspond to the first data unit on this medium that is encrypted with the given XTS-AES-[128,256] key. Note that “size” field in the following tables refers to the size of the element and not to the size of the encoded element.

⁵ The inclusion of initial tweak value facilitates use of several different keys for a single physical medium. For example, each key can correspond to a different sequence of LBAs residing on a physical drive. Another situation where the ability to specify the initial tweak value is needed is when only part of the encrypted data (i.e., a contiguous sequence of data units starting at some offset) is archived together with the corresponding key backup structure. It is impossible to decrypt this data without knowledge of the initial tweak value (i.e., the tweak value that corresponds to the first data unit in the archive).

Table 1 lists the elements of the key backup structure.

Table 1—Key backup structure

Element	Description	Reference
StructureID	Identifier of current structure	Table 2
Standard	Standard identifier	Table 3
KeyScope	Key scope	Table 4
Transform	Transform description	Table 5
KeyMaterial	Key material and its length	Table 7

7.1.2 Structure ID

Table 2 defines the StructureID element, which contains the information needed to uniquely identify a particular instance of a key backup structure.

Table 2—StructureID

Element	Size	XML Encoding	Description
ID	16 bytes	Base64	General identifier for the key backup structure.
Comment	Up to 1024 bytes	Text	A text description provided by the vendor.

7.1.3 Standard

Table 3 defines the Standard element, which contains information about the standard to which the data units were encrypted.

Table 3—Standard

Element	Size	XML Encoding	Description
StandardNumber	Up to 128 bytes	Text	Number of the standard used. Shall be IEEE STD 1619-2007.
StandardComment	Up to 256 bytes	Text	Any additional standard-related information.

7.1.4 KeyScope

The KeyScope specifies the scope of the key material that is identified in the key backup structure. The KeyScope is an ordered sequence of data units, numbered consecutively starting at a certain position. Table 4 defines the KeyScope element.

Table 4—KeyScope

Element	Size	XML Encoding	Description
KeyScopeStart	16 bytes	Integer	Value of the tweak associated with the first data unit in the scope.
DataUnitSize	16 bytes	Integer	The number of bits in one data unit that is covered by the current key.
KeyScopeLength	16 bytes	Integer	The number of data units that are covered by the current key.

7.1.5 Transform

Table 5 defines the Transform element.

Table 5—Transform

Element	Size	XML Encoding	Description
TransformName	Up to 16 bytes	Text	The transform name.

The transform name shall be one of the supported strings, as specified in Table 6.

Table 6—Supported Transforms

String	Description
XTS-AES-128	The XTS-AES-128 transform as defined in this standard.
XTS-AES-256	The XTS-AES-256 transform as defined in this standard.

7.1.6 KeyMaterial

Table 7 defines the KeyMaterial element. All key material is secret.

Table 7—KeyMaterial

Element	Size	XML Encoding	Description
KeyLength	2 bytes	Integer	Length (in bits) of the key. Allowed values are 256 (for XTS-AES-128) and 512 (for XTS-AES-256).
KeyValue	variable	Base64	The value of the key.

7.2 XML format

The key backup structure is encoded in XML, to facilitate a unified format and allow an application independent way of sharing key material. This also provides an automatic generation and parsing of the key backup structures. The Document Type Definition (DTD) for key backup format is shown in Figure 5.

```
<!ELEMENT KeyBackup (StructureID, Standard, KeyScope, Transform, KeyMaterial)>
  <!ELEMENT StructureID (ID, Comment?)>
    <!ELEMENT ID (#PCDATA)>
      <!ATTLIST ID Encoding CDATA #FIXED "Base64">

    </KeyMaterial>
  </KeyMaterial>
</KeyBackup>
```

Figure 6—XML document containing a key for a single key scope

7.3 Encryption of key backup material

A key backup structure may be protected as follows. The actual key material (KeyMaterial from Table 7) shall be wrapped encrypted with xml-enc (see XML-ENC, [B13]) and embedded within the XML key backup structure. XML-ENC does not mandate any single key wrapping algorithm, but implementations compliant with this standard shall support NIST AES CBC 256 (see XML-ENC, [B13]). Other key wrap algorithms allowed by XML-ENC may be used.

The keys that are used to wrap the key elements (KEK) may be referenced with xkms (see XML Key Management System, [B14]). The location of wrapping keys is not specified by this standard. The cryptographic strength of wrapping keys should be at least equivalent to the strength of the storage encryption keys wrapped (see NIST Key Management Guidelines [B9]). For example, an AES-256 bit key should be used to wrap an XTS-AES-256 key. The implementation should provide integrity for the key file, using standard methods.

In the example in Figure 7, the KeyMaterial is encrypted using AES-256 Key Wrap, whose wrapping key, referenced by the KeyInfo element, has identifier “WrapKey.” (This XML example corresponds to the unwrapped example in Figure 6.)

Base64 encoding of the wrapping key used in the example is as follows:

9s7VKp6PYK0XtYjs5OFBoqCDA3MmFd5tTqYnZv+PVro=

Annex B

(informative)

Test vectors

This annex lists several examples of applying XTS-AES-128 and XTS-AES-256. All numbers within specific test vectors in this annex are hexadecimal. For readability, the examples explicitly parse the XTS-AES key into Key_1 and Key_2 . All outputs are byte arrays (as opposed to hexadecimal numbers).

- PTX prefix denotes plaintext.
- CTX prefix denotes ciphertext.
- TWK prefix denotes the mask computed in step 1) in 5.3.1.

        for (j=0;j<AES_BLK_BYTES;j++)
        {
            Cout = (T[j] >> 7) & 1;
            T[j] = ((T[j] << 1) + Cin) & 0xFF;
            Cin = Cout;
        }
        if (Cout)
            T[0] ^= GF_128_FDBK;
    }
}
```

C.2 Encryption of a data unit with a size that is not a multiple of 16 bytes

```
#define GF_128_FDBK      0x87
#define AES_BLK_BYTES    16

void XTS_EncryptSector
(
    AES_Key &k2,                // key used for generating sector "tweak"
    AES_Key &k1,                // key used for "ECB" encryption
    u64b S,                    // sector number (64 bits)
    uint N,                    // sector size, in bytes
    const u08b *pt,            // plaintext sector input data
    u08b *ct                    // ciphertext sector output data
)
{
    uint i,j;                  // local counters
    u08b T[AES_BLK_BYTES];     // tweak value
    u08b x[AES_BLK_BYTES];     // local work value
    u08b Cin,Cout;              // "carry" bits for LFSR shifting

    assert(N >= AES_BLK_BYTES); // need at least a full AES block

    for (j=0;j<AES_BLK_BYTES;j++)
    {
        T[j] = (u08b) (S & 0xFF); // convert sector number to tweak plaintext
        S = S >> 8;                // also note that T[] is padded with zeroes
    }

    AES_ECB_Encrypt(k2,T);        // encrypt the tweak
    for (i=0;i+AES_BLK_BYTES <= N;i+=AES_BLK_BYTES)
    {
        // now encrypt the sector data
        // merge the tweak into the input block
        for (j=0;j<AES_BLK_BYTES;j++)
            x[j] = pt[i+j] ^ T[j];

        // encrypt one block
        AES_ECB_Encrypt(k1,x);

        // merge the tweak into the output block
        for (j=0;j<AES_BLK_BYTES;j++)
            ct[i+j] = x[j] ^ T[j];

        // LFSR "shift" the tweak value for the next location
        Cin = 0;
        for (j=0;j<AES_BLK_BYTES;j++)
        {
            Cout = (T[j] >> 7) & 1;
            T[j] = ((T[j] << 1) + Cin) & 0xFF;
            Cin = Cout;
        }
        if (Cout)
            T[0] ^= GF_128_FDBK;
    }

    if (i < N)                  // is there a final partial block to handle?
    {
        for (j=0;i+j<N;j++)
        {
            x[j] = pt[i+j] ^ T[j]; // copy in the final plaintext bytes
            ct[i+j] = ct[i+j-AES_BLK_BYTES]; // and copy out the final ciphertext bytes
        }
        for (;j<AES_BLK_BYTES;j++) // "steal" ciphertext to complete the block
            x[j] = ct[i+j-AES_BLK_BYTES] ^ T[j];
        // encrypt the final block
        AES_ECB_Encrypt(k1,x);

        // merge the tweak into the output block
        for (j=0;j<AES_BLK_BYTES;j++)
            ct[i+j-AES_BLK_BYTES] = x[j] ^ T[j];
    }
}
```

Annex D

(informative)

Rationale and design choices

D.1 Purpose

This annex provides some background material regarding design choices that were made in XTS-AES and the rationale behind these choices.

D.2 Transparent encryption

The starting point for this standard is a requirement that the transform be usable as transparent encryption. That is, it should be possible to insert an encryption/decryption module into existing data paths without having to change the data layout or message formats of other components on these data paths. In particular, transparent encryption can be implemented to occur in the host, along the data path from host to storage device, and inside the storage device, all without the need to modify the data transmission protocols or the layout of the data on the media. In the context of encryption by sector-level storage devices, this requirement translates into the following two constraints:

- 1) The transform must be *length-preserving*, namely the length of the ciphertext must equal that of the plaintext. This means that the transform must be deterministic, and that it cannot store an authentication tag along with the ciphertext.
- 2) The transform must be applicable to individual data-units (or sectors) independently of other data-units and in arbitrary order. This means that no chaining between different data-units is possible. This requirement stems from the need to support random access to the encrypted data. For example, encryption mode that chains multiple data units requires reading of several data units to decrypt a single unit.

Two solutions that were rejected by the group as insecure were to use either counter (CTR) mode or cipher block chaining (CBC) mode, deriving the IV from the sector number.

- Using CTR without authentication tags is trivially malleable, and an adversary with write access to the encrypted media can flip any bit of the plaintext simply by flipping the corresponding ciphertext bit.
- For CBC, an adversary with read/write access to the encrypted disk can copy a ciphertext sector from one position to another, and an application reading the sector off the new location will still get the same plaintext sector (except perhaps the first 128 bits). For example, this means that an adversary that is allowed to read a sector from the second position but not the first can find the content of the sector in first position by manipulating the ciphertext.
- For CBC, an adversary can flip any bit of the plaintext by flipping the corresponding ciphertext bit of the previous block, with the side-effect of “randomizing” the previous block.

The XTS-AES transform was chosen because it offers better protection against ciphertext manipulations and cut-and-paste attacks. It is important to realize, however, that regardless of the method used for encryption, the constraints above imply some inherent limitations on the level of security that can be achieved by such transform. As shown in the paragraphs that follow, these constraints imply that the best achievable security is essentially what can be obtained by using ECB mode with a different key per block (and using a cipher with wide blocks).

Specifically, since there are no authentication tags, any ciphertext (original or modified by adversary) will be decrypted as some plaintext and there is no built-in mechanism to detect alterations. The best that can be done is to ensure that any alternation of the ciphertext will completely randomize the plaintext, and rely on the application that uses this transform to include sufficient redundancy in its plaintext to detect and discard such random plaintexts.

Also, since this transform is deterministic, encrypting the plaintext twice with the same key and the same position will yield the same ciphertext. Moreover, since there is no chaining, an adversary can “mix and match” ciphertext units and get the same “mix and match” of their corresponding plaintext units. (Namely, if $C_0C_1\dots C_m$ is encryption of $P_0P_1\dots P_m$ and $C'_0C'_1\dots C'_m$ is encryption of $P'_0P'_1\dots P'_m$ then $C_0C'_1\dots C_m$ is encryption of $P_0P'_1\dots P_m$.)

The above “mix and match” weakness can be mitigated to some extent by using some context information in the encryption and decryption processes. In the case of sector-level encryption, the only context information that can be assumed to be available at both encryption and decryption is the (logical) position of the current data unit (as seen by the encryption/decryption module).⁶ Incorporating the position information into the encryption and decryption routines makes it possible to cryptographically hide the fact that the same unit is written in two different places, and also prevents “mix and match” between different positions. But as mentioned previously, even the best implementation of encryption by a sector-level storage device leaves several vulnerabilities. Three of these vulnerabilities are illustrated as follows:

- **Traffic analysis.** Consider an adversary that is able to passively observe the communication between the encrypting device and the disk. Since encryption is deterministic, this adversary is able to observe when a certain sector is written back to disk with a different value than was previously read from disk. This capability may help the adversary in mounting an attack based on traffic analysis.
- **Replay.** An adversary with read/write access to the encrypted disk can observe when a certain sector changes on the disk and then reset it to any one of its previous values. (Notice that this attack is not specific to transparent encryption; it may work even when using randomized encryption with authentication tags.)
- **Randomizing a sector.** Since there are no authentication tags, an adversary with write access to the encrypted disk can write an arbitrary ciphertext to any sector, causing an application that reads this sector to see a “random” plaintext instead of the value that was written to that sector. The behavior of the application on such “random” plaintext may be beneficial to the adversary.

When using transparent encryption, one must therefore address these vulnerabilities by means outside the scope of this standard.

D.3 Wide vs. narrow block tweakable encryption

In light of the previous discussion, the required interfaces of the transform are encryption and decryption routines as shown in Equation (5):

$$C = \text{Enc}(K, P, i) \text{ and } P = \text{Dec}(K, C, i) \quad (5)$$

where

- plaintext P and ciphertext C have the same length (i.e., the length of a single sector)
- K is the secret encryption key
- i represents the position information

⁶ On the other hand, parameters like “time of encryption” cannot be used as context information, since the decryption procedure typically has no way of obtaining that information.

The best security that one can hope for with such transform is that it looks to an adversary like a block cipher with block size equal to the sector size, and with different and independent keys for different values of i . Such a construct is called a “tweakable cipher” in the cryptographic literature. It was first defined formally by Liskov et al. in [B5].

Several constructions that achieve these properties exist in the cryptographic literature (e.g., see Halevi et al. [B1], [B2], [B3], and a construction based on Naor et al. [B8]). All these constructions, however, are rather expensive, requiring buffering of at least one sector worth of intermediate results and at least two passes over the entire sector.⁷ A cheaper alternative can be obtained by relaxing the requirement that the transform looks like a cipher with a wide (e.g., sector-length) block-size. Instead, one can work with narrow blocks of 128 bits, but still insist that different blocks (whether in the same or in different sectors) look to an adversary like they were encrypted with different independent keys.

Giving up the dependencies between different 128-bit blocks allows greater efficiency. The price for that, however, is that the attacks described in D.2 are now possible with finer granularity. Namely, whereas the adversary against a wide-block encryption scheme can do traffic analysis or replay with granularity of one sector, the adversary against a narrow-block encryption scheme can work with granularity of 128-bit blocks. Still, the consensus in the P1619 workgroup was that the added efficiency warrants this additional risk. Since these risks exist even with wide-block encryption—albeit with a coarser granularity—one would still need some other mechanisms for addressing them, and in many cases the same mechanisms can be used also for addressing these risks in their fine-grained form.

D.4 XEX construction

D.4.1 General XEX transform

In [B10], Rogaway described a construction of a narrow-block tweakable cipher from a standard cipher such as AES. That construction works as follows: the tweakable cipher uses two keys, K_1 and K_2 , both used as keys for the underlying cipher $\text{Enc}(K, \text{data})/\text{Dec}(K, \text{data})$. Given a plaintext block P and the tweak value, the tweak is parsed as a pair (s, t) (s can be thought of as the sector number and t as the block number within the sector). The construction first computes a mask value T using Equation (6):

$$T = \text{Enc}(K_2, s) \otimes \alpha^t \quad (6)$$

where

the multiplication is in $\text{GF}(2^n)$ (with n being the block-size of the underlying cipher)

α is a primitive element of $\text{GF}(2^n)$

Given plaintext P , ciphertext C is produced by Equation (7):

$$C = \text{Enc}(K_1, P \oplus T) \oplus T \quad (7)$$

Given ciphertext C , the plaintext P is produced Equation (8):

$$P = \text{Dec}(K_1, C \oplus T) \oplus T \quad (8)$$

⁷ At least some of this overhead appears to be inherent: Since these schemes insist on a block cipher with “wide block” (i.e., as wide as an entire sector), then every bit of ciphertext must “strongly depend” on every bit of plaintext and vice versa. This means in particular that no bit of output can be produced until all the input bits were processed by the block cipher.

D.4.2 Security of general XEX transform

The security analysis of generic XEX transform in Rogaway [B10] shows that this mode is secure as long as the number of blocks that are encrypted under the same key is sufficiently smaller than the birthday bound value of $2^{n/2}$, where n is the block size in bits of the underlying block cipher. Some attacks become possible when the number of blocks approaches the $2^{n/2}$ value.

The adversary analyzed in Rogaway [B10] can make arbitrary encryption and decryption queries to the tweakable cipher, using arbitrary tweak values. These queries are answered either by the construction above, or by a truly random collection of permutations and their inverses over $\{0,1\}^n$ (a different, independent permutation for every value of the tweak), and the adversary's goal is to determine which is the case. Rogaway proved in [B10], Theorem 8 that an adversary that makes at most q such queries cannot distinguish these two cases with advantage more than $4.5 q^2/2^n + \epsilon$ over a random guess (where ϵ is an error term that expresses the advantage of distinguishing the underlying cipher from a random permutation using q queries and n is the block size in bits of the underlying block cipher).

To explain the relevance of this analysis to the security of a real-world usage of the XTS-AES transform, the first argument is that no realistic adversary would have more information than the adversary in the attack model that is described in the analysis. This follows from the fact that adversary in Rogaway [B10] is assumed to be able to choose all the plaintext and ciphertext that is fed to the construction. Since the theorem (Rogaway [B10], Theorem 8) says that no adversary in that model can distinguish the construction from a collection of random permutations, it follows that no realistic adversary can distinguish between these cases with any significant advantage. This, in turn, means that an attack would be just as successful against a collection of truly random permutations, one per each 128-bit block, as it would be against XEX.

It follows that when analyzing the security of an application that uses the above scheme, one can think of the encryption as if it was done using a collection of truly random 128-bit permutations. When faced with such a collection of truly random permutations, the only information that the adversary has is the following:

- The same plaintext with the same tweak value will always be encrypted to the same ciphertext (cf. the traffic analysis attack from above).
- The same ciphertext with the same tweak value will always be decrypted to the same plaintext (cf. the replay attack from above).
- Any other ciphertext (plaintext) will be decrypted (encrypted) to a random value (cf. the randomizing attack from above).

In other words, the proof in Rogaway [B10] implies that except for the “error term” of $4.5 q^2/2^n + \epsilon$, the only attacks that are possible against XEX are the ones that are inherent from the use of transparent encryption with the granularity of n -bit blocks, where n is the block size in bits of the underlying cipher.

Some attacks against XEX are possible when the number of blocks q approaches the birthday bound. For example, consider a known-plaintext attack where the adversary sees q tuples of tweak, plaintext, and ciphertext. For each such tuple $[(s_i, t_i), P_i, C_i]$, denote by T_i the mask value that is computed from the tweak (s_i, t_i) .

From the birthday bound it follows that when q approaches $2^{n/2}$, there is a non-negligible probability that for some i, j there is a collision of the form shown in Equation (9):

$$P_i \oplus T_i = P_j \oplus T_j. \quad (9)$$

In this case, it also holds that [see Equation (10)]:

$$C_i \oplus T_i = \text{Enc}(K1, P_i \oplus T_i) = \text{Enc}(K1, P_j \oplus T_j) = C_j \oplus T_j. \quad (10)$$

Summing these two equalities implies

$$P_i \oplus C_i = P_j \oplus C_j$$

This can be used to distinguish XEX from a collection of truly random permutations. The adversary computes for all i the sum $S_i = P_i \oplus C_i$ and counts the number of pairs (i, j) for which $S_i = S_j$. The argument above implies that for any i, j , the probability that $S_i = S_j$ in ciphertext produced by XEX is roughly $2^{-n} + 2^{-n} = 2^{-n+1}$, where the first term is due to collision between i and j and the second term is due to equality $S_i = S_j$ without a collision. On the other hand, for truly random permutation the probability of $S_i = S_j$ is exactly 2^{-n} , and hence after observing roughly $2^{n/2}$ tuples $[(s_i, t_i), P_i, C_i]$ it is possible to distinguish ciphertext produced by XEX from a random sequence with non-negligible probability.

Given a collision between i and j as above, the following approach shows how the adversary can use his ability to create legally encrypted data for position i and ability to modify ciphertext in position j to modify the ciphertext at j so it will decrypt to an arbitrary adversary-controlled value.

As above, the adversary begins by computing the sums $S_i = C_i \oplus P_i$ and uses any equality $S_i = S_j$ as an evidence of collision between i and j . Denote by $[(s_i, t_i), P_i, C_i], [(s_j, t_j), P_j, C_j]$ the corresponding tweak, plaintext, and ciphertext values.

For some $\Delta \neq 0$, the adversary encrypts a new value $P'_i = P_i \oplus \Delta$ in position (s_i, t_i) , observes the corresponding ciphertext C'_i , and replaces the ciphertext block C_j by:

$$C'_j = C_j \oplus (C_i \oplus C'_i).$$

This new ciphertext block will be decrypted as $P'_j = P_j \oplus \Delta$. In other words, the adversary succeeded in “flipping” specific bits in plaintext corresponding to location j . To see this, observe Equation (11):

$$\begin{aligned} C'_j \oplus T_j &= C_j \oplus (C_i \oplus C'_i) \oplus T_j \\ &= C'_i \oplus (C_i \oplus C_j) \oplus T_j \\ &= C'_i \oplus (T_i \oplus T_j) \oplus T_j && \text{[follows from Equation (10)]} \\ &= C'_i \oplus T_i \end{aligned} \tag{11}$$

Therefore:

$$\text{Dec}(K1, C'_j \oplus T_j) = \text{Dec}(K1, C'_i \oplus T_i)$$

which implies that:

$$\begin{aligned} P'_j &= T_j \oplus \text{Dec}(K1, C'_j \oplus T_j) \\ &= T_j \oplus \text{Dec}(K1, C'_i \oplus T_i) && \text{[follows from Equation (11)]} \\ &= (T_j \oplus T_i) \oplus [T_i \oplus \text{Dec}(K1, C'_i \oplus T_i)] \\ &= (T_j \oplus T_i) \oplus P'_i \\ &= (T_j \oplus T_i) \oplus (P_i \oplus \Delta) \\ &= ((T_j \oplus T_i) \oplus P_i) \oplus \Delta \\ &= P_j \oplus \Delta. \end{aligned}$$

D.4.3 XTS-AES as a specific instantiation of general XEX

The XTS-AES-128 and XTS-AES-256 transforms described in this standard are concrete instantiations of the XEX scheme with AES as the underlying block cipher, and thus using $n = 128$ as the block length. A data unit sequence number (i.e., relative position) is used as a tweak in order to allow for copy or backup of a key scope or partial key scope of data encrypted with XTS-AES-[128,256] without re-encryption. In contrast to the generic XEX construction described in Rogaway [B10] that uses a single key, the XTS-

AES-128 and XTS-AES-256 modes in this standard use separate keys for tweaking and encryption purposes. This separation is a specific example of separation of key usage by purpose and is considered a good security design practice (see NIST Key Management Guidelines [B9], part 1, Section 5.2).

The expression $4.5 q^2/2^n$ is small enough as long as q is not much more than 2^{40} . The proof from Rogaway [B10] yields strong security guarantee as long as the same key is not used to encrypt much more than a terabyte of data (which gives $q = 2^{36}$ blocks). For this case, no attack can succeed with probability better than 2^{-53} (i.e., approximately one in eight quadrillion).

This security guarantee deteriorates as more data is encrypted under the same key. For example, when using the same key for a petabyte of data, attacks such as in D.4.2 have success probability of at most approximately 2^{-37} (i.e., approximately eight in a trillion), and with exabyte, of data the success probability is at most approximately 2^{-17} (i.e., approximately eight in a million).

The decision on the maximum amount of data to be encrypted with a single key should take into account the above calculations together with the practical implication of the described attack (e.g., ability of the adversary to modify plaintext of a specific block, where the position of this block may not be under adversary's control).

D.5 Sector-size that is not a multiple of 128 bits

The generic XEX transform as described in Rogaway [B10] immediately implies a method for encrypting sectors that consist of an integral number of 128-bit blocks: apply the transform individually to each 128-bit block, but use the block number in the sector as part of the tweak value when encrypting that block. This method is applicable to the most common sector sizes (such as 512 bytes or 4096 bytes). However, it does not directly apply to sector sizes that are not an integer multiple of 128-bit blocks (e.g., 520-byte sectors).

To encrypt a sector with a length that is not an integral number of 128-bit blocks, the standard uses the “ciphertext-stealing” technique similar to the one used for ECB mode (see Meyer et. al. [B7], Figure 2-22). Namely, both XTS-AES-128 and XTS-AES-256 encrypt all the full blocks except the last full block (with different tweak values for each block), and then encrypt the last full block together with the remaining partial block using two applications of the XTS-AES-blockEnc procedure described in 5.3.1 with two different tweak values, as described in 5.3.2.

D.6 Miscellaneous

Following are general remarks about appropriate use of the XTS-AES transform:

- When analyzing the security of an application that uses this standard, one must consider the methods that were used to generate the keys. As with every cryptographic algorithm, it is important that the secret-key used for XTS-AES-[128,256] be chosen at random (or from a “cryptographically strong” pseudo-random source). Indeed, all security guarantees (including the security claims of the theorem from Rogaway [B10]) are null and void if the key is chosen from a low entropy source. The issues of strong pseudo-randomness and key-generation are outside the scope of this standard. For further information, see NIST Key Management Guidelines [B9].
- Use of a single cryptographic key for more than a few hundred terabytes of data opens possibility of attacks, as described in D.4.3. The limitation on the size of data encrypted with a single key is not unique to this standard. It comes directly from the fact that AES has a block size of 128 bits and is not mitigated by using AES with a 256-bit key.
